

Security Blanket Enterprise Edition

Security Blanket Enterprise Edition is a software tool that provides central Administration Console management of all your Linux operating systems and allows you to automatically assess and lock down groups of servers based on industry standard guidelines. Security Blanket is web-based allowing access from any location. The Administration Console is easy to use with an intuitive web front end, enabling the System Administrator to perform security assessments and security configurations through Scan and Apply activities. Assessment and baseline reporting allow the System Administrator to capture the security state of a Group of servers and compare an earlier baseline with the current security state, providing valuable compliancy information.

Security Blanket Enterprise Edition is an ideal solution for organizations with any number of Linux servers, however organizations with a small number of servers may find that the Standalone version of the product meets their needs better than the Enterprise Edition. Enterprise Edition allows System Administrators to Group servers requiring the same security settings and associate industry standard lock down Profiles or User Defined Profiles to the server Group. Each system in the Group is scanned against the selected Profile and a Group Assessment Report is generated showing which systems are compliant with the Profile Modules and which systems fail. The servers in the group can then be automatically locked down to the specifications of the Profile selected. Organizations may have different lock down policies for internet facing servers than they do for test servers, for example. The flexibility of Security Blanket Enterprise Edition gives System Administrators the ability to centrally manage any number of Linux servers and by applying chosen Profiles, configure the OSs of each server to the specific lock downs based on need and company policy.

Security Blanket Enterprise Edition Benefits

An easy to use Administration Console for system assessment and remediation. The Security Blanket Enterprise Edition Administration Console provides an intuitive graphical user interface and easy navigation to identify Clients (individual servers), define Groups of Clients, associate lock down Profiles, run system scans, and automatically apply actions to configure the operating systems for all servers within the Group.

Easy to manage security Profiles. Security Modules are the lock down guidelines that make up a security Profile. Predefined security Profiles from CIS, SANS and the UNIX DISA STIGs are provided in the standard application. If your organization requires specific security policy guidelines; enabling Modules, disabling Modules, or changing Module parameters, can easily be done to create User Defined Profiles.

Clear and concise descriptions and tips are provided for every security Module. Additionally, Security Blanket Enterprise Edition provides a cross-reference between Modules to the guidelines it satisfied. This cross-reference can be invaluable when a System Administrator requires data for a security audit.

Easy to manage actions for remediation. Security Modules within a Profile can be selected or de-selected allowing system administrators to manage exactly what will be configured during the remediation of a Group of servers.

Automatic lock down. Once the Profile is selected and the Modules within the Profile selected or de-selected, the System Administrator can Apply (configure) the operating systems of all Clients within the Group to be compliant with the chosen Profile.
